

Restaurant Suite vs Foodics

This view updates the earlier markdown comparison with the new Flutter applications and backend gap closures completed in this turn.

Current Position

The product is now stronger than the original repo snapshot because it no longer stops at backend-only dine-in operations. It now has runnable Flutter role workspaces for Customer, Waiter, Cashier, Kitchen, and Owner, plus a customer loyalty and order-history flow.

Where This Iteration Closed The Gap

Area	What Was Added Here	Why It Matters Against Foodics
Customer product layer	Customer app, restaurants listing, order history	Foodics only has a CRM and loyalty. This new package has a wider ecosystem.
Cashier maturity	Split-tender capable payment flow and payment history	Foodics explicitly offers richer dine-in payment handling; this makes the OS backend layer closer to an actual cashier.
Owner visibility	Payment mix, branch performance, loyalty metrics	This makes the OS backend layer closer to an actual owner.
Operational UI completeness	Flutter workspaces for waiter, cashier, kitchen	The previous repo state had backend capability without the frontend.

Where Foodics Still Stays Ahead

- Wider packaged ecosystem: marketplace, broader integrations, and mature omnichannel layers.
- Online ordering breadth: storefronts, delivery orchestration, and deeper ecosystem partnerships.
- Enterprise packaging: more battle-tested onboarding, payments, and support motion across many branches.
- Commercial polish: stronger breadth of polished operational edge cases out of the box.

Recommended Positioning

- Position the product as the customizable Egypt-focused restaurant operating system, not as a total feature superset of Foodics.
- Lead with table service UX, customer linkage, ownership visibility, and implementation flexibility.
- Use Foodics as the benchmark to explain roadmap direction, not as a claim that the platform is already broader everywhere.
